

# Linear Regression using Stata

(v. 6.3)

*Oscar Torres-Reyna*  
*otorres@princeton.edu*

We use regression to estimate the unknown effect of changing one variable over another (Stock and Watson, 2003, ch. 4)

When running a regression we are making two assumptions, 1) there is a linear relationship between two variables (i.e. X and Y) and 2) this relationship is additive (i.e.  $Y = x_1 + x_2 + \dots + x_N$ ).

Technically, linear regression estimates how much Y changes when X changes one unit.

In Stata use the command regress, type:

```
regress [dependent variable] [independent variable(s)]  
regress y x
```

In a multivariate setting we type:

```
regress y x1 x2 x3 ...
```

Before running a regression it is recommended to have a clear idea of what you are trying to estimate (i.e. which are your outcome and predictor variables).

A regression makes sense only if there is a sound theory behind it.

**Example:** Are SAT scores *higher* in states that spend more money on education controlling by other factors?\*

- Outcome (Y) variable – SAT scores, variable csat in dataset
- Predictor (X) variables
  - Per pupil expenditures primary & secondary (expense)
  - % HS graduates taking SAT (percent)
  - Median household income (income)
  - % adults with HS diploma (high)
  - % adults with college degree (college)
  - Region (region)

\***Source:** Data and examples come from the book *Statistics with Stata (updated for version 9)* by Lawrence C. Hamilton (chapter 6). [Click here](http://www.duxbury.com/highered/) to download the data or search for it at <http://www.duxbury.com/highered/>. Use the file states.dta (educational data for the U.S.).

# Regression: variables

It is recommended first to examine the variables in the model to check for possible errors, type:

```
use http://dss.princeton.edu/training/states.dta
```

```
describe csat expense percent income high college region
```

```
summarize csat expense percent income high college region
```

```
. describe csat expense percent income high college region
```

variable name	storage type	display format	value label	variable label
csat	int	%9. 0g		Mean composite SAT score
expense	int	%9. 0g		Per pupil expenditures prim&sec
percent	byte	%9. 0g		% HS graduates taking SAT
income	double	%10. 0g		Median household income, \$1, 000
high	float	%9. 0g		% adults HS diploma
college	float	%9. 0g		% adults college degree
region	byte	%9. 0g	region	Geographical region

```
. summarize csat expense percent income high college region
```

Variable	Obs	Mean	Std. Dev.	Min	Max
csat	51	944. 098	66. 93497	832	1093
expense	51	5235. 961	1401. 155	2960	9259
percent	51	35. 76471	26. 19281	4	81
income	51	33. 95657	6. 423134	23. 465	48. 618
high	51	76. 26078	5. 588741	64. 3	86. 6
college	51	20. 02157	4. 16578	12. 3	33. 3
region	50	2. 54	1. 128662	1	4

# Regression: what to look for

Lets run the regression:

```
regress csat expense, robust
```

Outcome variable (Y)

Predictor variable (X)

Robust standard errors (to control for heteroskedasticity)

```
regress csat expense, robust
```

Linear regression

7 Root MSE: root mean squared error, is the sd of the regression. The closer to zero better the fit.

Number of obs = 51  
F( 1, 49) = 36.80  
Prob > F = 0.0000  
R-squared = 0.2174  
Root MSE = 59.814

csat	Coef.	Robust Std. Err.	t	P> t	[95% Conf. Interval ]
expense	- .0222756	.0036719	- 6.07	0.000	-.0296547
_cons	1060.732	24.35468	43.55	0.000	1011.79

$$csat = 1061 - 0.022 * expense$$

For each one-point increase in expense, SAT scores decrease by 0.022 points.

The t-values test the hypothesis that the coefficient is different from 0. To reject this, you need a t-value greater than 1.96 (for 95% confidence). You can get the t-values by dividing the coefficient by its standard error. The t-values also show the importance of a variable in the model.

1 This is the p-value of the model. It tests whether  $R^2$  is different from 0. Usually we need a p-value lower than 0.05 to show a statistically significant relationship between X and Y.

2 R-square shows the amount of variance of Y explained by X. In this case expense explains 22% of the variance in SAT scores.

3 Adj R<sup>2</sup> (not shown here) shows the same as  $R^2$  but adjusted by the # of cases and # of variables. When the # of variables is small and the # of cases is very large then Adj  $R^2$  is closer to  $R^2$ . This provides a more honest association between X and Y.

4 Two-tail p-values test the hypothesis that each coefficient is different from 0. To reject this, the p-value has to be lower than 0.05 (you could choose also an alpha of 0.10). In this case, expense is statistically significant in explaining SAT.

# Regression: what to look for

Adding the rest of predictor variables:

`regress csat expense percent income high college, robust`

Output variable (Y)

Predictor variables (X)

1

This is the p-value of the model. It indicates the reliability of X to predict Y. Usually we need a p-value lower than 0.05 to show a statistically significant relationship between X and Y.

`regress csat expense percent income high college, robust`

Linear regression

Number of obs =	51
F( 5, 45) =	50.90
Prob > F =	0.0000
R-squared =	0.8243
Root MSE =	29.571

7

Root MSE: root mean squared error, is the sd of the regression. The closer to zero better the fit.

2

R-square shows the amount of variance of Y explained by X. In this case the model explains 82.43% of the variance in SAT scores.

csat	Coef.	Robust Std. Err.	t	P> t	[95% Conf. Interval ]
expense	.0033528	.004781	0.70	0.487	-.0062766 .0129823
percent	-2.618177	.2288594	-11.44	0.000	-3.079123 -2.15723
income	.1055853	1.207246	0.09	0.931	-2.325933 2.537104
high	1.630841	.943318	1.73	0.091	-.2690989 3.530781
college	2.030894	2.113792	0.96	0.342	-2.226502 6.28829
_cons	851.5649	57.28743	14.86	0.000	736.1821 966.9477

$$\text{csat} = 851.56 + 0.003*\text{expense} \\ - 2.62*\text{percent} + 0.11*\text{income} + 1.63*\text{high} \\ + 2.03*\text{college}$$

The t-values test the hypothesis that the coefficient is different from 0. To reject this, you need a t-value greater than 1.96 (at 0.05 confidence). You can get the t-values by dividing the coefficient by its standard error. The t-values also show the importance of a variable in the model. In this case, percent is the most important.

5

4

3

Two-tail p-values test the hypothesis that each coefficient is different from 0. To reject this, the p-value has to be lower than 0.05 (you could choose also an alpha of 0.10). In this case, expense, income, and college are not statistically significant in explaining SAT; high is almost significant at 0.10. Percent is the only variable that has some significant impact on SAT (its coefficient is different from 0).

## Regression: using dummy variables/selecting the reference category

If using categorical variables in your regression, you need to add  $n-1$  dummy variables. Here 'n' is the number of categories in the variable. In the example below, variable 'industry' has twelve categories (type `tab industry`, or `tab industry, nolabel`)

The easiest way to include a set of dummies in a regression is by using the prefix "i." By default, the first category (or lowest value) is used as reference. For example:

```
sysuse nlsw88.dta
reg wage hours i.industry, robust
```

```
Linear regression
Number of obs = 2228
F( 12, 2215) = 24.96
Prob > F = 0.0000
R-squared = 0.0800
Root MSE = 5.5454
```

wage	Robust					
	Coef.	Std. Err.	t	P> t	[95% Conf. Interval]	
hours	.0723658	.0110213	6.57	0.000	.0507526	.093979
industry						
Mining	9.328331	7.287849	1.28	0.201	-4.963399	23.62006
Construction	1.858089	1.281807	1.45	0.147	-.6555808	4.371759
Manufacturing	1.415641	.849571	1.67	0.096	-.2503983	3.081679
Transport/Comm/Utility	5.432544	1.03998	5.22	0.000	3.393107	7.471981
Wholesale/Retail Trade	.4583809	.8548564	0.54	0.592	-2.128023	2.134785
Finance/Ins/Real Estate	3.92933	.9934195	3.96	0.000	1.981199	5.877461
Business/Repair Svc	1.990151	1.054457	1.89	0.059	-.0776775	4.057979
Personal Services	-1.018771	.8439617	-1.21	0.228	-2.67381	.6362679
Entertainment/Rec Svc	1.111801	1.192314	0.93	0.351	-1.226369	3.449972
Professional Services	2.094988	.8192781	2.56	0.011	.4883548	3.701622
Public Administration	3.232405	.8857298	3.65	0.000	1.495457	4.969352
_cons	3.126629	.8899074	3.51	0.000	1.381489	4.871769

To change the reference category to "Professional services" (category number 11) instead of "Ag/Forestry/Fisheries" (category number 1), use the prefix "ib#." where "#" is the number of the reference category you want to use; in this case is 11.

```
sysuse nlsw88.dta
reg wage hours ib11.industry, robust
```

```
Linear regression
Number of obs = 2228
F( 12, 2215) = 24.96
Prob > F = 0.0000
R-squared = 0.0800
Root MSE = 5.5454
```

wage	Robust					
	Coef.	Std. Err.	t	P> t	[95% Conf. Interval]	
hours	.0723658	.0110213	6.57	0.000	.0507526	.093979
industry						
Ag/Forestry/Fisheries	-2.094988	.8192781	-2.56	0.011	-3.701622	-.4883548
Mining	7.233343	7.245913	1.00	0.318	-6.97615	21.44284
Construction	-.2368991	1.011309	-0.23	0.815	-2.220112	1.746314
Manufacturing	-.6793477	.3362365	-2.02	0.043	-1.338719	-.019976
Transport/Comm/Utility	3.337556	.6861828	4.86	0.000	1.991927	4.683185
Wholesale/Retail Trade	-1.636607	.3504059	-4.67	0.000	-2.323766	-.949449
Finance/Ins/Real Estate	1.834342	.6171526	2.97	0.003	.6240837	3.0446
Business/Repair Svc	-.1048377	.7094241	-0.15	0.883	-1.496044	1.286368
Personal Services	-3.113759	.3192289	-9.75	0.000	-3.739779	-2.48774
Entertainment/Rec Svc	-.983187	.9004471	-1.09	0.275	-2.748996	.7826217
Public Administration	1.137416	.4176899	2.72	0.007	.3183117	1.956521
_cons	5.221617	.4119032	12.68	0.000	4.41386	6.029374

The "ib#" option is available since Stata 11 (type `help fvvarlist` for more options/details). For older Stata versions you need to use "xi:" along with "i." (type `help xi` for more options/details). For the examples above type (output omitted):

```
xi: reg wage hours i.industry, robust
char industry[omit]11 /*Using category 11 as reference*/
xi: reg wage hours i.industry, robust
```

To create dummies as variables type  
`tab industry, gen(industry)`

To include all categories by suppressing the constant type:  
`reg wage hours bn.industry, robust hascons`

If you run the regression without the ‘robust’ option you get the ANOVA table

xi: regress *csat expense percent income high college i.region*

Source	SS	df	MS	Number of obs	=	50
Model	(A) 200269. 84	9	22252. 2045 (D)	F( 9, 40)	=	70. 13
Residual	(B) 12691. 5396	40	317. 28849 (E)	Prob > F	=	0. 0000
Total	(C) 212961. 38	49	4346. 15061 (F)	R-squared	=	0. 9404

$$F = \frac{\frac{MSS}{(k-1)}}{\frac{RSS}{n-k}} = \frac{\frac{200269.84}{9}}{\frac{12691.5396}{40}} = \frac{22252.2045}{317.28849} = \frac{D}{E} = 70.13$$

$$AdjR^2 = 1 - \frac{n-1}{n-k}(1-R^2) = 1 - \frac{49}{40}(1-0.9404) = 1 - \frac{E}{F} = 1 - \frac{317.28849}{4346.15061} = 0.9270$$

$$R^2 = \frac{MSS}{TSS} = 1 - \frac{\sum e_i^2}{\sum (y_i - \bar{y})^2} = \frac{200269.84}{212961.38} = \frac{A}{C} = 0.9404$$

$$RootMSE = \sqrt{\frac{RSS}{(n-k)}} = \sqrt{\frac{12691.5396}{40}} = \sqrt{\frac{B}{40}} = 17.813$$

A = Model Sum of Squares (MSS). The closer to TSS the better fit.

B = Residual Sum of Squares (RSS)

C = Total Sum of Squares (TSS)

D = Average Model Sum of Squares = MSS/(k-1) where k = # predictors

E = Average Residual Sum of Squares = RSS/(n - k) where n = # of observations

F = Average Total Sum of Squares = TSS/(n - 1)

$R^2$  shows the amount of observed variance explained by the model, in this case 94%.

The F-statistic, F(9,40), tests whether  $R^2$  is different from zero.

Root MSE shows the average distance of the estimator from the mean, in this case 18 points in estimating SAT scores.

## Regression: estto/esttab

To show the models side-by-side you can use the commands `estto` and `esttab`:

```
regress csat expense, robust
eststo model1
regress csat expense percent income high college, robust
eststo model2
xi: regress csat expense percent income high college i.region, robust
eststo model3
esttab, r2 ar2 se scalar(rmse)
. esttab, r2 ar2 se scalar(rmse)
```

	(1) csat	(2) csat	(3) csat
expense	<b>-0.0223***</b> (0.00367)	<b>0.00335</b> (0.00478)	<b>-0.00202</b> (0.00359)
percent		<b>-2.618***</b> (0.229)	<b>-3.008***</b> (0.236)
income		<b>0.106</b> (1.207)	<b>-0.167</b> (1.196)
high		<b>1.631</b> (0.943)	<b>1.815</b> (1.027)
college		<b>2.031</b> (2.114)	<b>4.671**</b> (1.600)
_Iregion_2			<b>69.45***</b> (18.00)
_Iregion_3			<b>25.40*</b> (12.53)
_Iregion_4			<b>34.58***</b> (9.450)
percent2			
_cons	<b>1060.7***</b> (24.35)	<b>851.6***</b> (57.29)	<b>808.0***</b> (67.86)
N	51	51	50
R-sq	0.217	0.824	0.911
adj. R-sq	0.201	0.805	0.894
rmse	59.81	29.57	21.49

Standard errors in parentheses  
 \* p<0.05, \*\* p<0.01, \*\*\* p<0.001

Type `help eststo` and `help esttab`  
 for more options.

## Regression: correlation matrix

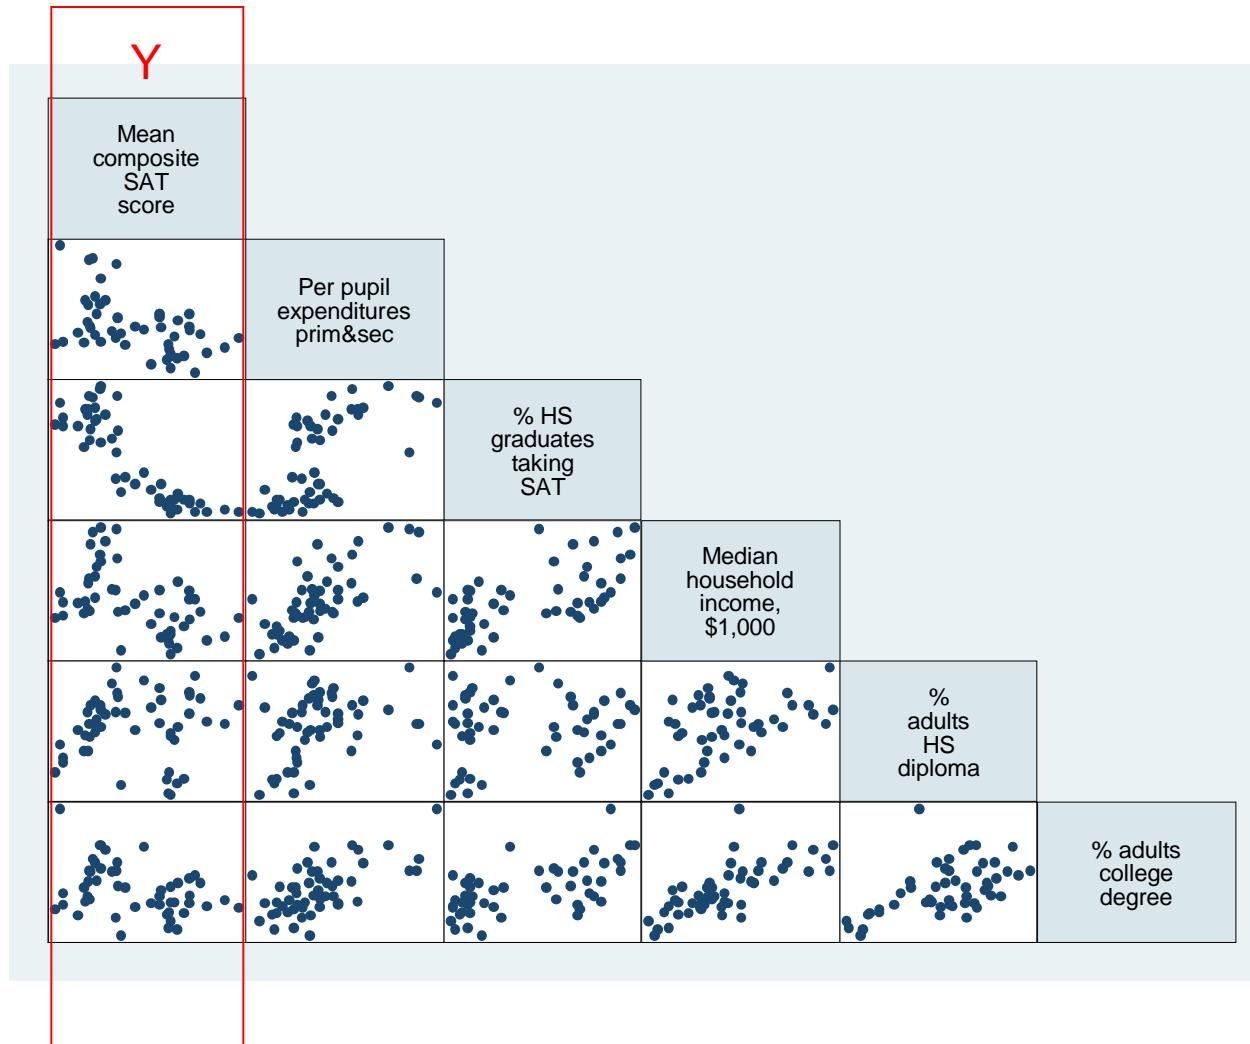

Below is a correlation matrix for all variables in the model. Numbers are Pearson correlation coefficients, go from -1 to 1. Closer to 1 means strong correlation. A negative value indicates an inverse relationship (roughly, when one goes up the other goes down).

		csat	expense	percent	income	high	college
csat		1. 0000					
expense		- 0. 4663*	1. 0000				
percent		0. 0006	- 0. 8758*	0. 6509*	1. 0000		
income		0. 0000	- 0. 4713*	0. 6784*	0. 6733*	1. 0000	
high		0. 0005	0. 0000	0. 0000	0. 0000	0. 0001	1. 0000
college		0. 5495	0. 0252	0. 3226	0. 1413	0. 5099*	0. 0001
		- 0. 3729*	0. 6400*	0. 6091*	0. 7234*	0. 5319*	1. 0000
		0. 0070	0. 0000	0. 0000	0. 0000	0. 0001	

## Regression: graph matrix

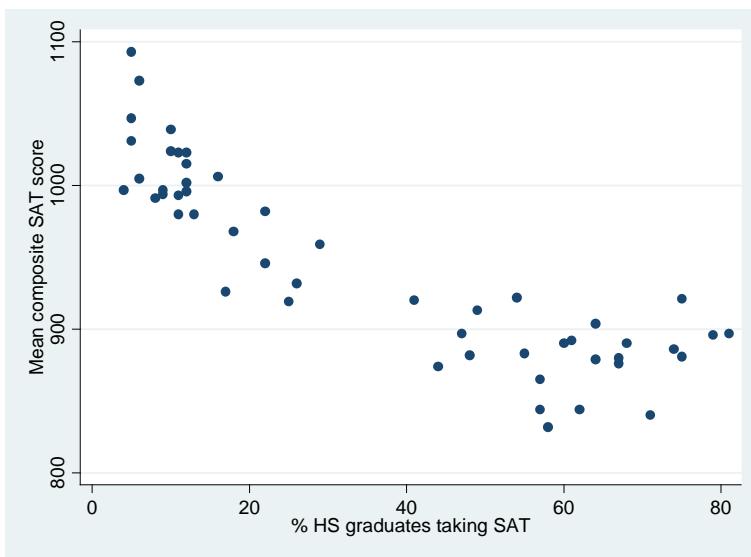

Command `graph matrix` produces a graphical representation of the correlation matrix by presenting a series of scatterplots for all variables. Type:

```
graph matrix csat expense percent income high college, half  
maxis(ylabel(none) xlabel(none))
```

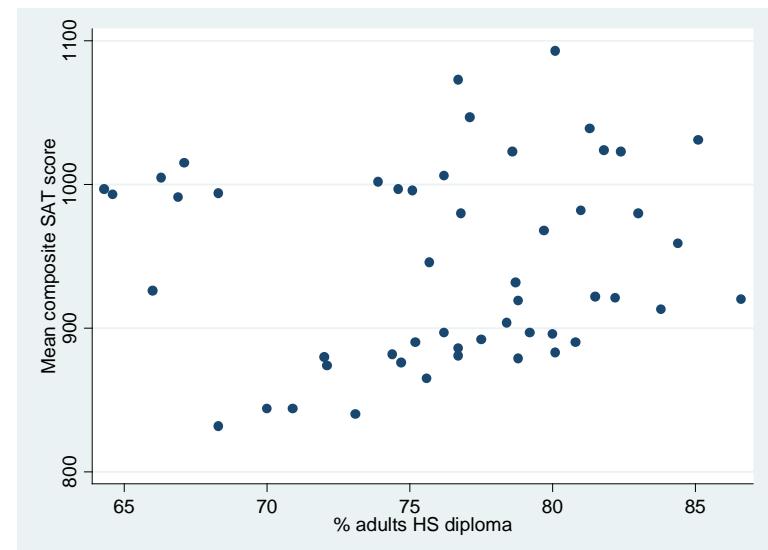

# Regression: exploring relationships

scatter csat percent

scatter csat high

There seem to be a curvilinear relationship between csat and percent , and slightly linear between csat and high. To deal with U-shaped curves we need to add a square version of the variable, in this case percent square

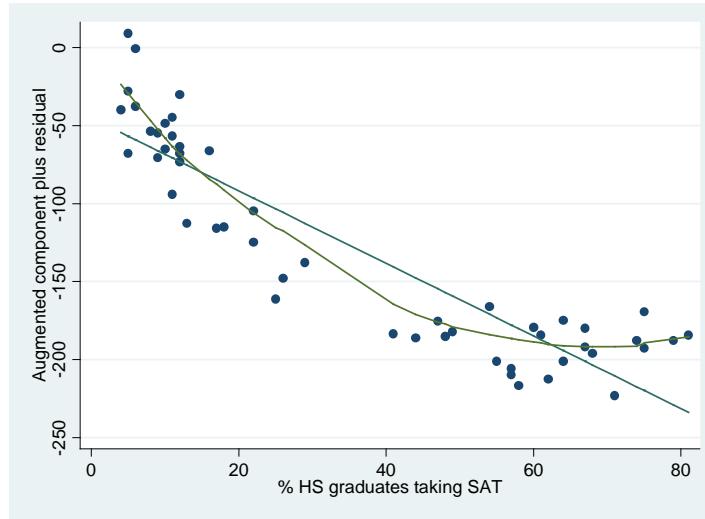

```
generate percent2 = percent^2
```

## Regression: functional form/linearity

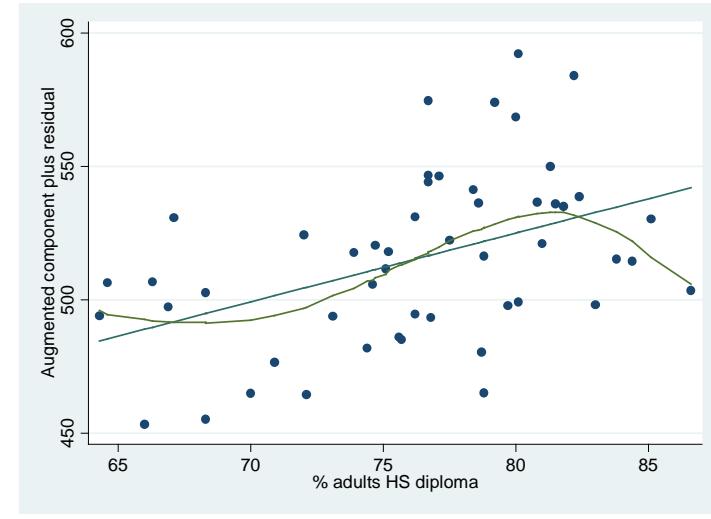

The command `acprplot` (augmented component-plus-residual plot) provides another graphical way to examine the relationship between variables. It does provide a good testing for linearity. Run this command after running a regression

```
regress csat percent high /* Notice we do not include percent2 */
acprplot percent, lowess
acprplot high, lowess
```

acprplot percent, lowess

acprplot high, lowess

The option `lowess` (locally weighted scatterplot smoothing) draws the observed pattern in the data to help identify nonlinearities. `Percent` shows a quadratic relation, it makes sense to add a square version of it. `High` shows a polynomial pattern as well but goes around the regression line (except on the right). We could keep it as is for now.

The model is:

```
xi: regress csat expense percent percent2 income high college i.region, robust
```

For more details see <http://www.ats.ucla.edu/stat/stata/webbooks/reg/chapter2/statareg2.htm>, and/or type `help acprplot` and `help lowess`. 13

# Regression: models

```

xi: regress csat expense percent percent2 income high college i.region, robust
eststo model4
esttab, r2 ar2 se scalar(rmse)
    . esttab, r2 ar2 se scalar(rmse)

```

	(1) csat	(2) csat	(3) csat	(4) csat
expense	-0.0223*** (0.00367)	0.00335 (0.00478)	-0.00202 (0.00359)	0.00141 (0.00372)
percent		-2.618*** (0.229)	-3.008*** (0.236)	-5.945*** (0.641)
i ncome		0.106 (1.207)	-0.167 (1.196)	-0.914 (0.973)
hi gh		1.631 (0.943)	1.815 (1.027)	1.869 (0.931)
college		2.031 (2.114)	4.671** (1.600)	3.418** (1.145)
_Iregion_2			69.45*** (18.00)	5.077 (20.75)
_Iregion_3			25.40* (12.53)	5.209 (10.42)
_Iregion_4			34.58*** (9.450)	19.25* (8.110)
percent2				0.0460*** (0.0102)
_cons	1060.7*** (24.35)	851.6*** (57.29)	808.0*** (67.86)	874.0*** (58.13)
N	51	51	50	50
R-sq	0.217	0.824	0.911	0.940
adj. R-sq	0.201	0.805	0.894	0.927
rmse	59.81	29.57	21.49	17.81

Standard errors in parentheses  
 \* p<0.05, \*\* p<0.01, \*\*\* p<0.001

How good the model is will depend on how well it predicts  $Y$ , the linearity of the model and the behavior of the residuals.

There are two ways to generate the *predicted values of Y* (usually called  $Y_{hat}$ ) given the model:

Option A, using `generate` after running the regression:

```
xi: regress csat expense percent percent2 income high college i.region, robust  
generate csat_predict = _b[_cons] + _b[percent]*percent + _b[percent]*percent + _b[percent2]*percent2  
+ _b[high]*high + ...
```

Option B, using `predict` immediately after running the regression:

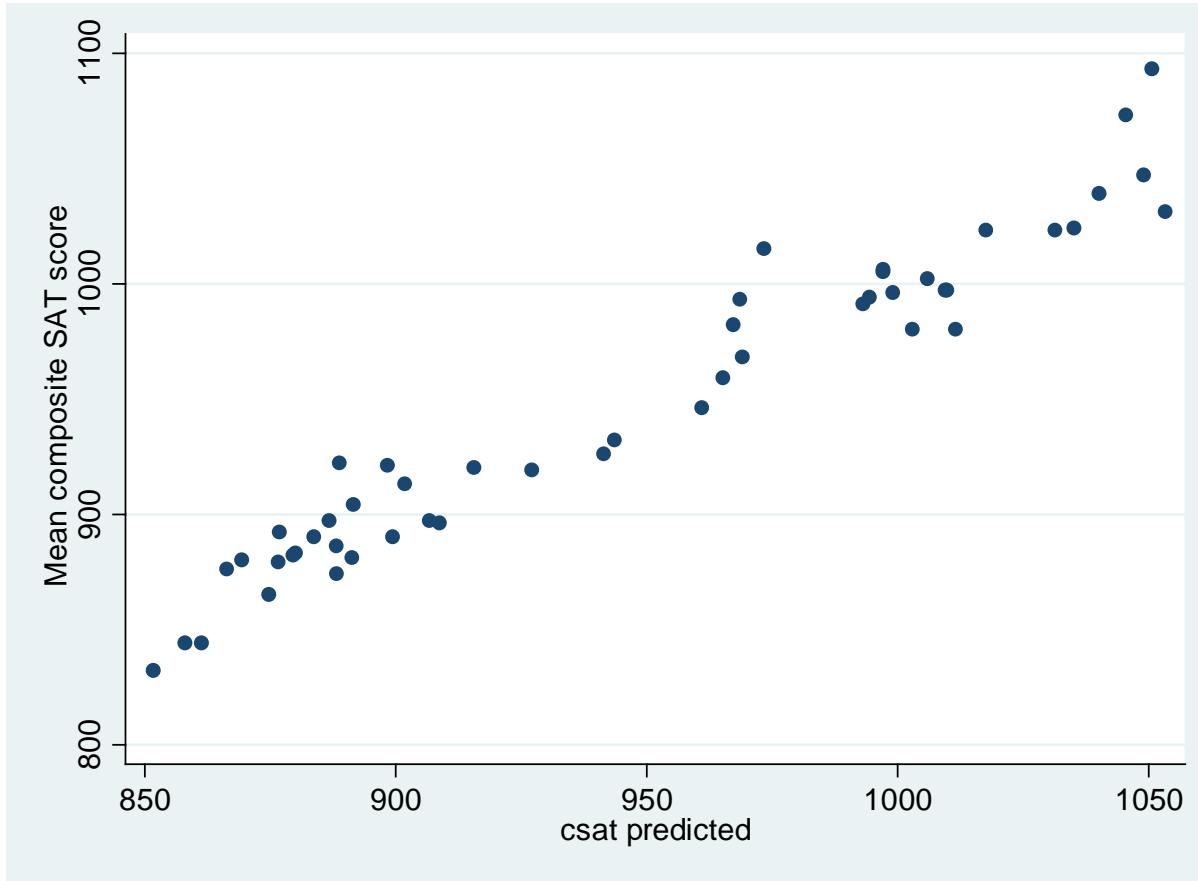

```
xi: regress csat expense percent percent2 income high college i.region, robust  
predict csat_predict  
label variable csat_predict "csat predicted"
```

```
. predict csat_predict  
(option xb assumed; fitted values)  
(1 missing value generated)  
. label variable csat_predict "csat predicted"
```

## Regression: observed vs. predicted values

For a quick assessment of the model run a scatter plot

```
scatter csat csat_predict
```

We should expect a 45 degree pattern in the data. Y-axis is the observed data and x-axis the predicted data ( $\hat{Y}$ ).

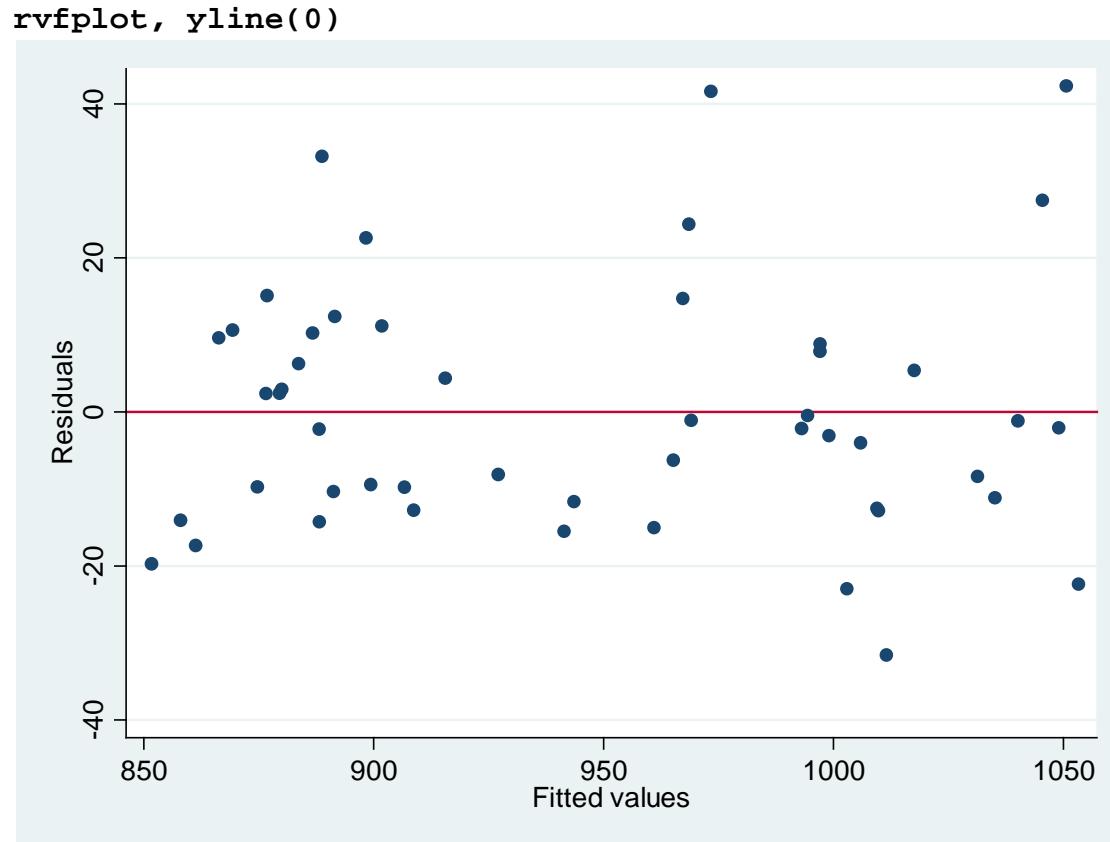

In this case the model seems to be doing a good job in predicting csat

## Regression: testing for homoskedasticity

An important assumption is that the variance in the residuals has to be homoskedastic or constant. Residuals cannot vary for lower or higher values of  $X$  (i.e. fitted values of  $Y$  since  $Y=Xb$ ). A definition:

"The error term [e] is homoskedastic if the variance of the conditional distribution of  $[e_i]$  given  $X_i$  [ $\text{var}(e_i|X_i)$ ], is constant for  $i=1\dots n$ , and in particular does not depend on  $x$ ; otherwise, the error term is heteroskedastic" (Stock and Watson, 2003, p.126)

When plotting residuals vs. predicted values ( $\hat{Y}$ ) we *should not observe* any pattern at all. In Stata we do this using `rvfplot` right after running the regression, it will automatically draw a scatterplot between residuals and predicted values.

Residuals seem to slightly expand at higher levels of  $\hat{Y}$ .

A non-graphical way to detect heteroskedasticity is the Breusch-Pagan test. The null hypothesis is that residuals are homoskedastic. In the example below we fail to reject the null at 95% and concluded that residuals are homogeneous. However at 90% we reject the null and conclude that residuals are not homogeneous.

```
estat hettest
. estat hettest

Breusch-Pagan / Cook-Weisberg test for heteroskedasticity
Ho: Constant variance
Variables: fitted values of csat

chi 2(1)      =     2.72
Prob > chi 2   =    0.0993
```

The graphical and the Breush-Pagan test suggest the possible presence of heteroskedasticity in our model. The problem with this is that we may have the wrong estimates of the standard errors for the coefficients and therefore their t-values.

There are two ways to deal with this problem, one is using heteroskedasticity-robust standard errors, the other one is using weighted least squares (see Stock and Watson, 2003, chapter 15). WLS requires knowledge of the conditional variance on which the weights are based, if this is known (rarely the case) then use WLS. In practice it is recommended to use heteroskedasticity-robust standard errors to deal with heteroskedasticity.

By default Stata assumes homoskedastic standard errors, so we need to adjust our model to account for heteroskedasticity. To do this we use the option `robust` in the `regress` command.

```
xi: regress csat expense percent percent2 income high college i.region, robust
```

Following Stock and Watson, as a rule-of-thumb, you should always assume heteroskedasticity in your model (see Stock and Watson, 2003, chapter 4) .

## Regression: omitted-variable test

*How do we know we have included all variables we need to explain Y?*

Testing for omitted variable bias is important for our model since it is related to the assumption that the error term and the independent variables in the model are not correlated ( $E(e|X) = 0$ )

If we are missing variables in our model and

- “is correlated with the included regressor” and,
- “the omitted variable is a determinant of the dependent variable” (Stock and Watson, 2003, p.144),

...then our regression coefficients are inconsistent.

In Stata we test for omitted-variable bias using the ovtest command:

```
xi: regress csat expense percent percent2 income high college i.region, robust  
ovtest
```

```
. ovtest
```

```
Ramsey RESET test using powers of the fitted values of csat  
Ho: model has no omitted variables  
F(3, 37) = 1.25  
Prob > F = 0.3068
```

The null hypothesis is that the model does not have omitted-variables bias, the p-value is higher than the usual threshold of 0.05 (95% significance), so we fail to reject the null and conclude that we do not need more variables.

## Regression: specification error

Another command to test model specification is `linktest`. It basically checks whether we need more variables in our model by running a new regression with the observed  $Y$  (`csat`) against  $\hat{Y}$  (`csat_predicted` or  $X\beta$ ) and  $\hat{Y}^2$ -squared as independent variables<sup>1</sup>.

The thing to look for here is the significance of `_hatsq`. The null hypothesis is that there is no specification error. If the p-value of `_hatsq` is not significant then we fail to reject the null and conclude that our model is correctly specified. Type:

```
xi: regress csat expense percent percent2 income high college i.region, robust  
linktest
```

```
. linktest
```

Source	SS	df	MS	Number of obs	=	50

<sup>1</sup> For more details see <http://www.ats.ucla.edu/stat/stata/webbooks/reg/chapter2/statareg2.htm>, and/or type `help linktest`.

## Regression: multicollinearity

An important assumption for the multiple regression model is that independent variables are *not perfectly multicolinear*. One regressor should not be a linear function of another.

When multicollinearity is present *standard errors may be inflated*. Stata will drop one of the variables to avoid a division by zero in the OLS procedure (see Stock and Watson, 2003, chapter 5).

The Stata command to check for multicollinearity is `vif` (variance inflation factor). Right after running the regression type:

```
. vif
```

Variable	VIF	1/VIF
percent2	70.80	0.014124
percent	49.52	0.020193
_Iregion_2	8.47	0.118063
income	4.97	0.201326
_Iregion_3	4.89	0.204445
high	4.71	0.212134
college	4.52	0.221348
expense	3.33	0.300111
_Iregion_4	2.14	0.467506
Mean VIF	17.04	

A  $vif > 10$  or a  $1/vif < 0.10$  indicates trouble.

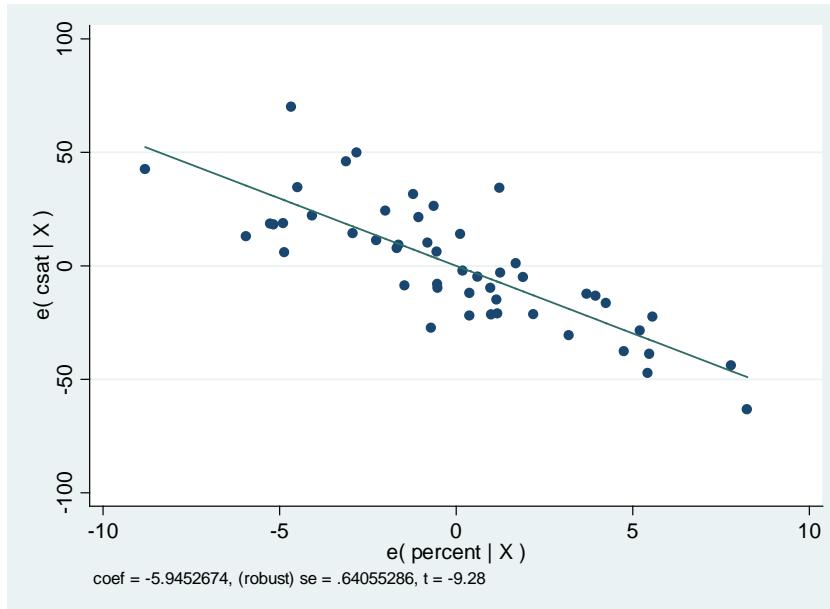

We know that percent and percent2 are related since one is the square of the other. They are ok since percent has a quadratic relationship with Y, *but this would be an example of multicollinearity*.

The rest of the variables look ok.

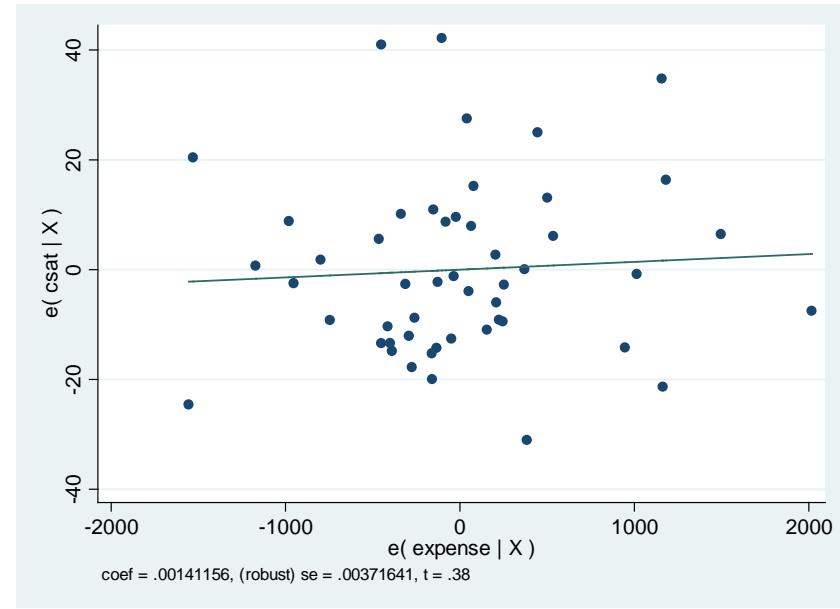

## Regression: outliers

To check for outliers we use the `avplots` command (added-variable plots). Outliers are data points with extreme values that could have a negative effect on our estimators. After running the regression type:

avplot percent

avplot expense

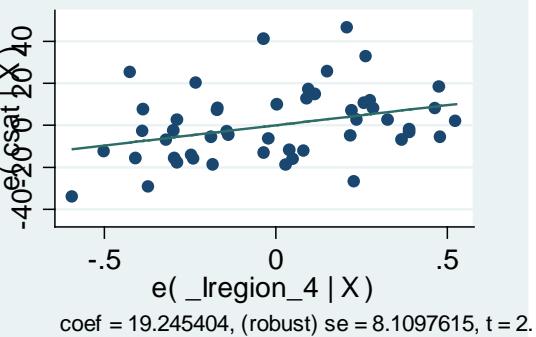

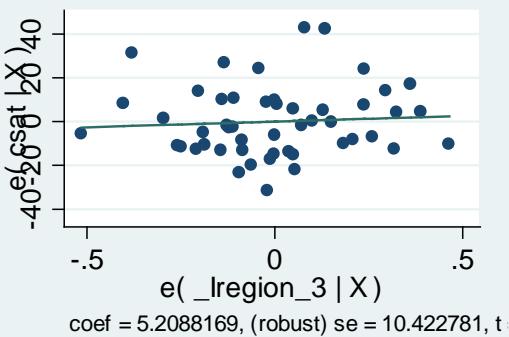

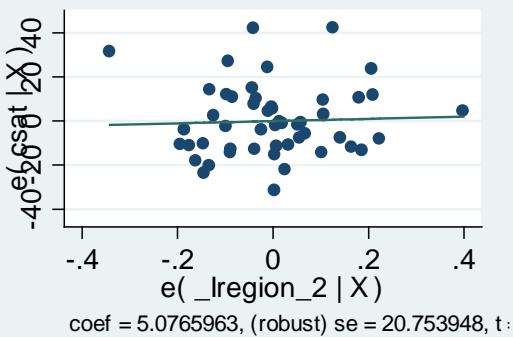

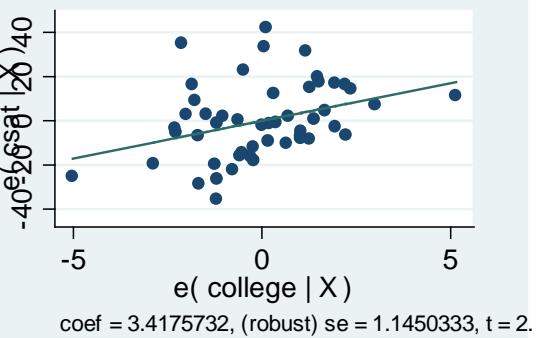

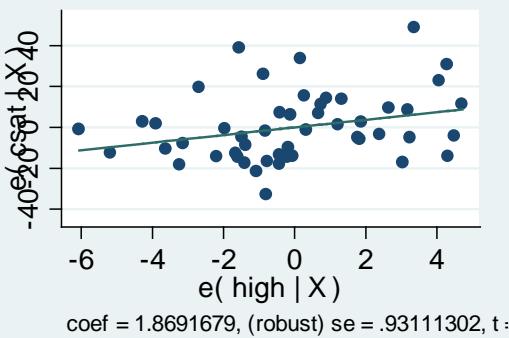

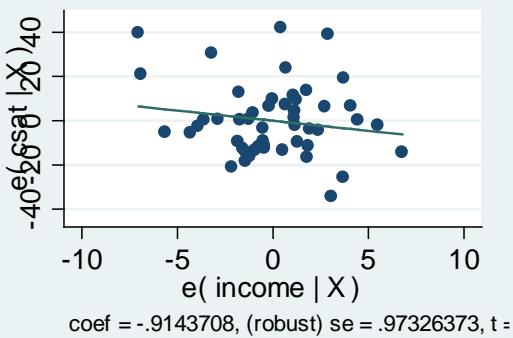

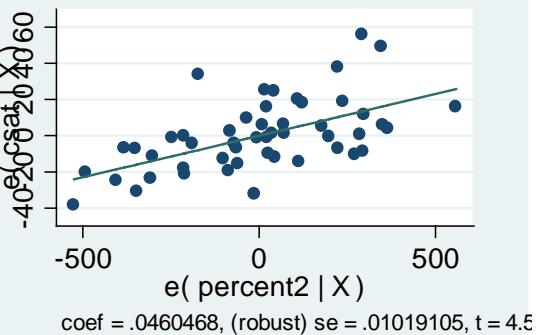

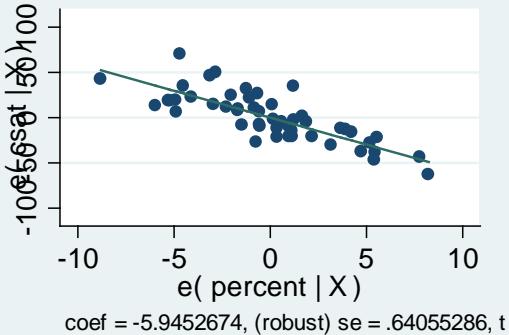

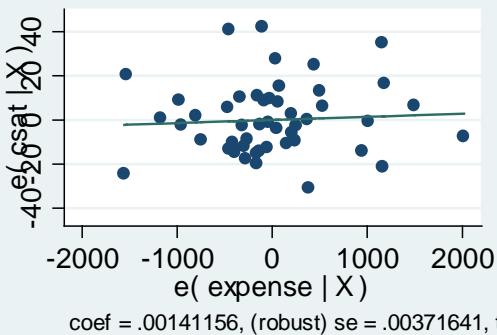

These plots regress each variable against all others, notice the coefficients on each. All data points seem to be in range, no outliers observed.

For more details and tests on this and influential and leverage variables please check  
<http://www.ats.ucla.edu/stat/stata/webbooks/reg/chapter2/statareg2.htm>

Also type `help diagplots` in the Stata command window.

# Regression: outliers

- *An Introduction to Econometrics Using Stata*/Christopher F. Baum, Stata Press, 2006
- *Statistics with Stata (updated for version 9)* / Lawrence Hamilton, Thomson Books/Cole, 2006
- UCLA <http://www.ats.ucla.edu/stat/stata/webbooks/reg/chapter2/statareg2.htm>

Another assumption of the regression model (OLS) that impact the validity of all tests (p, t and F) is that residuals behave ‘normal’. Residuals (here indicated by the letter “e”) are the difference between the observed values (Y) and the predicted values (Yhat):  $e = Y - \hat{Y}$ .

In Stata you type: `predict e, resid.` It will generate a variable called “e” (residuals).

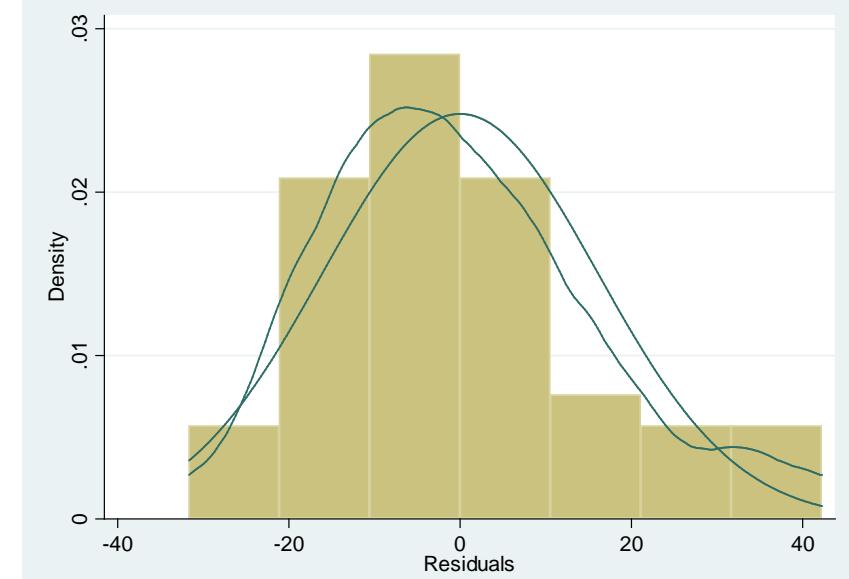

Three graphs will help us check for normality in the residuals: `kdensity`, `pnorm` and `qnorm`.

**kdensity e, normal**

A kernel density plot produces a kind of histogram for the residuals, the option `normal` overlays a normal distribution to compare. Here residuals seem to follow a normal distribution. Below is an example using `histogram`.

**histogram e, kdensity normal**

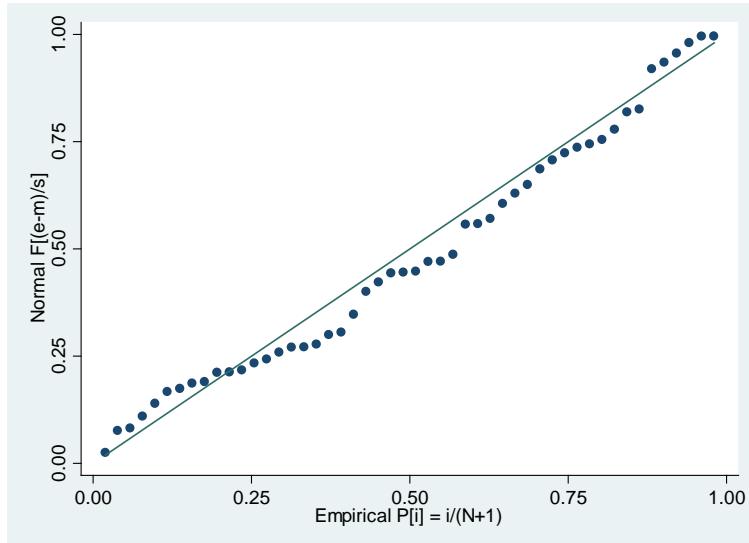

If residuals do not follow a ‘normal’ pattern then you should check for omitted variables, model specification, linearity, functional forms. In sum, you may need to reassess your model/theory. In practice normality does not represent much of a problem when dealing with really big samples.

## Regression: testing for normality

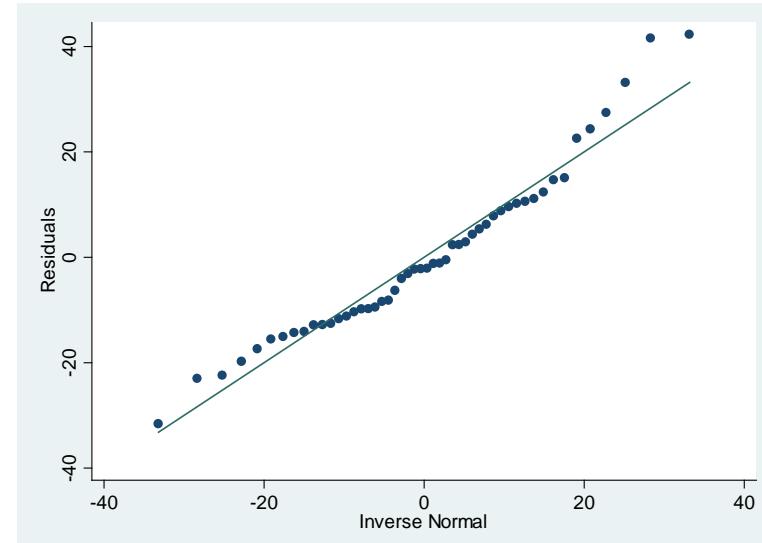

Standardize normal probability plot (`pnorm`) checks for non-normality in the middle range of residuals. Again, slightly off the line but looks ok.

`pnorm e`

Quintile-normal plots (`qnorm`) check for non-normality in the extremes of the data (tails). It plots quintiles of residuals vs quintiles of a normal distribution. Tails are a bit off the normal.

`qnorm e`

A non-graphical test is the Shapiro-Wilk test for normality. It tests the hypothesis that the distribution is normal, in this case the null hypothesis is that the distribution of the residuals is normal. Type

`swilk e`    . `swilk e`

Shapiro-Wilk W test for normal data

Variable	Obs	W	V	z	Prob>z
e	50	0.95566	2.085	1.567	0.05855

The null hypothesis is that the distribution of the residuals is normal, here the p-value is 0.06 we failed to reject the null (at 95%). We conclude then that residuals are normally distributed, with the caveat that they are not at 90%.

To test whether two coefficients are jointly different from 0 use the command `test` (see Hamilton, 2006, p.175).

```
xi: quietly regress csat expense percent percent2 income high college i.region, robust
Note 'quietly' suppress the regression output
```

To test the null hypothesis that *both* coefficients do not have any effect on `csat` ( $\beta_{high} = 0$  and  $\beta_{college} = 0$ ), type:

```
test high college
```

```
. test high college
( 1) high = 0
( 2) college = 0
F(  2,     40) =    17.12
                 Prob > F =    0.0000
```

The p-value is 0.0000, we reject the null and conclude that *both* variables have indeed a significant effect on SAT.

Some other possible tests are (see Hamilton, 2006, p.176):

```
test income = 1
test high = college
test income = (high + college)/100
```

Stata temporarily stores the coefficients as `_b[varname]`, so if you type:

```
gen percent_b = _b[percent]
gen constant_b = _b[_cons]
```

You can also save the standard errors of the variables `_se[varname]`

```
gen percent_se = _se[percent]
gen constant_se = _se[_cons]
```

. **summarize percent\_b percent\_se constant\_b constant\_se**

Variable	Obs	Mean	Std. Dev.	Min	Max
percent_b	51	-5.945267	0	-5.945267	-5.945267
percent_se	51	.6405529	0	.6405529	.6405529
constant_b	51	873.9537	0	873.9537	873.9537
constant_se	51	58.12895	0	58.12895	58.12895

# Regression: saving regression coefficients/getting predicted values

You can see a list of stored results by typing after the regression `ereturn list`:

```
. xi: quietly regress csat expense percent percent2 income high college i.region, robust  
i.region          _Iregion_1-4          (naturally coded; _Iregion_1 omitted)  
. ereturn list

Type `help return` for more details

The following are general guidelines for building a regression model\*

1. Make sure all relevant predictors are included. These are based on your research question, theory and knowledge on the topic.
2. Combine those predictors that tend to measure the same thing (i.e. as an index).
3. Consider the possibility of adding interactions (mainly for those variables with large effects)
4. Strategy to keep or drop variables:
  1. Predictor not significant and has the expected sign -> Keep it
  2. Predictor not significant and does not have the expected sign -> Drop it
  3. Predictor is significant and has the expected sign -> Keep it
  4. Predictor is significant but does not have the expected sign -> Review, you may need more variables, it may be interacting with another variable in the model or there may be an error in the data.

# Regression: publishing regression output (`outreg2`)

The command `outreg2` gives you the type of presentation you see in academic papers. It is important to notice that `outreg2` is not a Stata command, it is a user-written procedure, and you need to install it by typing (only the first time)

```
ssc install outreg2
```

Follow this example (letters in italics you type)

```
use "H:\public_html\Stata\Panel101.dta", clear  
reg y x1, r  
outreg2 using myreg.doc, replace ctitle(Model 1)
```

```
. outreg2 using myreg.doc, replace ctitle(Model 1)  
myreg.doc   
dir : seeout
```

Windows users click here to open the file `myreg.doc` in Word (you can replace this name with your own). Otherwise follow the Mac instructions.

Mac users click here to go to the directory where `myreg.doc` is saved, open it with Word (you can replace this name with your own)

You can add other model (using variable `x2`) by using the option `append`  
(NOTE: make sure to close `myreg.doc`)

```
reg y x1 x2, r  
outreg2 using myreg.doc, append ctitle(Model 2)  
  
. outreg2 using myreg.doc, append ctitle(Model 2)  
myreg.doc  
dir : seeout
```

You also have the option to export to Excel, just use the extension `*.xls`.

For older versions of `outreg2`, you may need to specify the option `word` or `excel` (after comma)

VARIABLES	(1) Model 1
x1	4.950e+08 (6.902e+08)
Constant	1.524e+09** (6.636e+08)

# Regression: publishing regression output (outreg2)

You can use outreg2 for almost any regression output (linear or no linear). In the case of logit models with odds ratios, you need to add the option eform, see below

```
use "H:\public_html\Stata\Panel101.dta", clear  
logit y_bin x1  
outreg2 using mymod.doc, replace ctitle(Logit coeff)  
. outreg2 using mymod.doc, replace ctitle(Logit coeff)  
mymod.doc  
dir : seeout
```

```
logit y_bin x1, or  
outreg2 using mymod.doc, append ctitle(Odds ratio) eform
```

```
. outreg2 using mymod.doc, append ctitle(Odds ratio) eform  
mymod.doc  
dir : seeout
```

Windows users click here to open the file mymod.doc in Word (you can replace this name with your own). Otherwise follow the Mac instructions.

Mac users click here to go to the directory where mymod.doc is saved, open it with Word (you can replace this name with your own)

EQUATION	VARIABLES	(1) Logit coeff	(2) Odds ratio
y_bin	x1	0.493 (0.645)	1.637 (1.055)
	Constant	1.082** (0.482)	2.952** (1.422)

For more details/options type  
help outreg2

Observations	70	70
Standard errors in parentheses		
*** p<0.01, ** p<0.05, * p<0.1		

# **Regression: publishing regression output (`outreg2`)**

For predicted probabilities and marginal effects, see the following document

<http://dss.princeton.edu/training/Margins.pdf>

# Regression: interaction between dummies

Interaction terms are needed whenever there is reason to believe that the effect of one independent variable depends on the value of another independent variable. We will explore here the interaction between two dummy (binary) variables. In the example below there could be the case that the effect of student-teacher ratio on test scores may depend on the percent of English learners in the district\*.

- Dependent variable (Y) – Average test score, variable `testscr` in dataset.
- Independent variables (X)
  - Binary `hi_str`, where '0' if student-teacher ratio (`str`) is lower than 20, '1' equal to 20 or higher.
    - In Stata, first generate `hi_str = 0` if `str<20`. Then replace `hi_str=1` if `str>=20`.
  - Binary `hi_el`, where '0' if English learners (`el_pct`) is lower than 10%, '1' equal to 10% or higher
    - In Stata, first generate `hi_el = 0` if `el_pct<10`. Then replace `hi_el=1` if `el_pct>=10`.
  - Interaction term `str_el` = `hi_str * hi_el`. In Stata: generate `str_el = hi_str*hi_el`

We run the regression

```
regress testscr hi_el hi_str str_el, robust
```

Linear regression						
	Robust	Std. Err.	t	P> t	[95% Conf. Interval]	
<code>hi_el</code>	-18.16295	2.345952	-7.74	0.000	-22.77435	-13.55155
<code>hi_str</code>	-1.907842	1.932215	-0.99	0.324	-5.705964	1.890279
<code>str_el</code>	-3.494335	3.121226	-1.12	0.264	-9.629677	2.641006
<code>_cons</code>	664.1433	1.388089	478.46	0.000	661.4147	666.8718

The equation is `testscr_hat = 664.1 - 18.1*hi_el - 1.9*hi_str - 3.5*str_el`

The effect of `hi_str` on the tests scores is -1.9 but given the interaction term (and assuming all coefficients are significant), the net effect is  $-1.9 - 3.5 \cdot hi\_el$ . If `hi_el` is 0 then the effect is -1.9 (which is `hi_str` coefficient), but if `hi_el` is 1 then the effect is  $-1.9 - 3.5 = -5.4$ . In this case, the effect of student-teacher ratio is more negative in districts where the percent of English learners is higher.

See the next slide for more detailed computations.

\*The data used in this section is the "California Test Score" data set (`caschool.dta`) from chapter 6 of the book *Introduction to Econometrics* from Stock and Watson, 2003. Data can be downloaded from [http://wps.aw.com/aw\\_stock\\_ie\\_2/50/13016/3332253.cw/index.html](http://wps.aw.com/aw_stock_ie_2/50/13016/3332253.cw/index.html). For a detailed discussion please refer to the respective section in the book.

## Regression: interaction between dummies (cont.)

You can compute the expected values of test scores given different values of hi\_str and hi\_el. To see the effect of hi\_str given hi\_el type the following right after running the regression in the previous slide.

```
. predict yhat1 if hi_str==0 & hi_el==0  
(option xb assumed; fitted values)  
(271 missing values generated)  
  
. predict yhat2 if hi_str==1 & hi_el==0  
(option xb assumed; fitted values)  
(341 missing values generated)  
  
. predict yhat3 if hi_str==0 & hi_el==1  
(option xb assumed; fitted values)  
(331 missing values generated)  
  
. predict yhat4 if hi_str==1 & hi_el==1  
(option xb assumed; fitted values)  
(317 missing values generated)
```

These are different scenarios holding constant hi\_el and varying hi\_str. Below we add some labels

- . label variable yhat1 "Low str/Low el"
- . label variable yhat2 "High str/Low el"
- . label variable yhat3 "Low str/High el"
- . label variable yhat4 "High str/High el"

We then obtain the average of the estimations for the test scores (for all four scenarios, notice same values for all cases).

```
. summarize yhat1 yhat2 yhat3 yhat4
```

variable	obs	Mean	Std. Dev.	Min	Max
yhat1	149	664.1433	0	664.1433	664.1433
yhat2	79	662.2355	0	662.2355	662.2355
yhat3	89	645.9803	0	645.9803	645.9803
yhat4	103	640.5782	0	640.5782	640.5782

```
. display 664.1 - 662.2  
1.9  
  
. display 645.9 - 640.5  
5.4  
  
. display 5.4 - 1.9  
3.5
```

Here we estimate the net effect of low/high student-teacher ratio holding constant the percent of English learners. When hi\_el is 0 the effect of going from low to high student-teacher ratio goes from a score of 664.2 to 662.2, a difference of 1.9. From a policy perspective you could argue that moving from high str to low str improve test scores by 1.9 in low English learners districts.

When hi\_el is 1, the effect of going from low to high student-teacher ratio goes from a score of 645.9 down to 640.5, a decline of 5.4 points (1.9+3.5). From a policy perspective you could say that reducing the str in districts with high percentage of English learners could improve test scores by 5.4 points.

## Regression: interaction between a dummy and a continuous variable

Lets explore the same interaction as before but we keep student-teacher ratio continuous and the English learners variable as binary. The question remains the same\*.

- Dependent variable (Y) – Average test score, variable `testscr` in dataset.
- Independent variables (X)
  - Continuous `str`, student-teacher ratio.
  - Binary `hi_el`, where '0' if English learners (`el_pct`) is lower than 10%, '1' equal to 10% or higher
  - Interaction term `str_el2 = str * hi_el`. In Stata: generate `str_el2 = str*hi_el`

We will run the regression

```
regress testscr str hi_el str_el2, robust
```

. regress testscr str hi_el str_el2, robust						
Linear regression						
					Number of obs = 420	
					F( 3, 416) = 63.67	
					Prob > F = 0.0000	
					R-squared = 0.3103	
					Root MSE = 15.88	
		Robust				
testscr		Coef.	Std. Err.	t	P> t	[95% Conf. Interval]
str		-.9684601	.5891016	-1.64	0.101	-.2.126447 .1895268
hi_el		5.639141	19.51456	0.29	0.773	-.32.72029 43.99857
str_el2		-1.276613	.9669194	-1.32	0.187	-.3.17727 .6240436
_cons		682.2458	11.86781	57.49	0.000	658.9175 705.5742

The equation is  $\text{testscr}_{\hat{}} = 682.2 - 0.97*\text{str} + 5.6*\text{hi\_el} - 1.28*\text{str\_el2}$

The effect of `str` on `testscr` will be mediated by `hi_el`.

- If `hi_el` is 0 (low) then the effect of `str` is  $682.2 - 0.97*\text{str}$ .
- If `hi_el` is 1 (high) then the effect of `str` is  $682.2 - 0.97*\text{str} + 5.6 - 1.28*\text{str} = 687.8 - 2.25*\text{str}$

Notice that how `hi_el` changes both the intercept and the slope of `str`. Reducing `str` by one in low EL districts will increase test scores by 0.97 points, but it will have a higher impact (2.25 points) in high EL districts. The difference between these two effects is 1.28 which is the coefficient of the interaction (Stock and Watson, 2003, p.223).

\*The data used in this section is the "California Test Score" data set (`caschool.dta`) from chapter 6 of the book *Introduction to Econometrics* from Stock and Watson, 2003. Data can be downloaded from [http://wps.aw.com/aw\\_stock\\_ie\\_2/50/13016/3332253.cw/index.html](http://wps.aw.com/aw_stock_ie_2/50/13016/3332253.cw/index.html). For a detailed discussion please refer to the respective section in the book.

## Regression: interaction between two continuous variables

Lets keep now both variables continuous. The question remains the same\*.

- Dependent variable (Y) – Average test score, variable `testscr` in dataset.
- Independent variables (X)
  - Continuous `str`, student-teacher ratio.
  - Continuous `el_pct`, percent of English learners.
  - Interaction term `str_el3 = str * el_pct`. In Stata: generate `str_el3 = str*el_pct`

We will run the regression

```
regress testscr str el_pct str_el3, robust
```

Linear regression						
						Number of obs = 420
						F( 3, 416) = 155.05
						Prob > F = 0.0000
						R-squared = 0.4264
						Root MSE = 14.482
testscr	Coef.	Robust Std. Err.	t	P> t	[95% Conf. Interval]	
str	-1.117018	.5875135	-1.90	0.058	-2.271884	.0378468
el_pct	-.6729116	.3741231	-1.80	0.073	-1.408319	.0624958
str_el3	.0011618	.0185357	0.06	0.950	-.0352736	.0375971
_cons	686.3385	11.75935	58.37	0.000	663.2234	709.4537

The equation is `testscr_hat = 686.3 - 1.12*str - 0.67*el_pct + 0.0012*str_el3`

The effect of the interaction term is very small. Following Stock and Watson (2003, p.229), algebraically the slope of `str` is  $-1.12 + 0.0012*el\_pct$  (remember that `str_el3` is equal to `str*el_pct`). So:

- If `el_pct = 10`, the slope of `str` is  $-1.108$
- If `el_pct = 20`, the slope of `str` is  $-1.096$ . A difference in effect of 0.012 points.

In the continuous case there is an effect but is very small (and not significant). See Stock and Watson, 2003, for further details.

\*The data used in this section is the “California Test Score” data set (`caschool.dta`) from chapter 6 of the book *Introduction to Econometrics* from Stock and Watson, 2003. Data can be downloaded from [http://wps.aw.com/aw\\_stock\\_ie\\_2/50/13016/3332253.cw/index.html](http://wps.aw.com/aw_stock_ie_2/50/13016/3332253.cw/index.html). For a detailed discussion please refer to the respective section in the book.

# Creating dummies

You can create dummy variables by either using `recode` or using a combination of `tab/gen` commands:  
`tab major, generate(major_dum)`

Major	Freq.	Percent	Cum.
ECON	10	33.33	33.33
MATH	10	33.33	66.67
POLITICS	10	33.33	100.00
Total	30	100.00	

Check the ‘variables’ window, at the end you will see three new variables. Using `tab1` (for multiple frequencies) you can check that they are all 0 and 1 values

Variables	
Name	Label
city	City
state	State
gender	Gender
status	Status: grad or undergrad
major	Major
country	Country
age	Age
sat	SAT
score	Average score (grade)
height	Height (in)
readnews	Newspaper read / week
score2	Score in decimals
readnews2	Monthly readership
agegroups	Age by groups
sex	Gender
major_dum1	major==Econ
major_dum2	major==Math
major_dum3	major==Politics

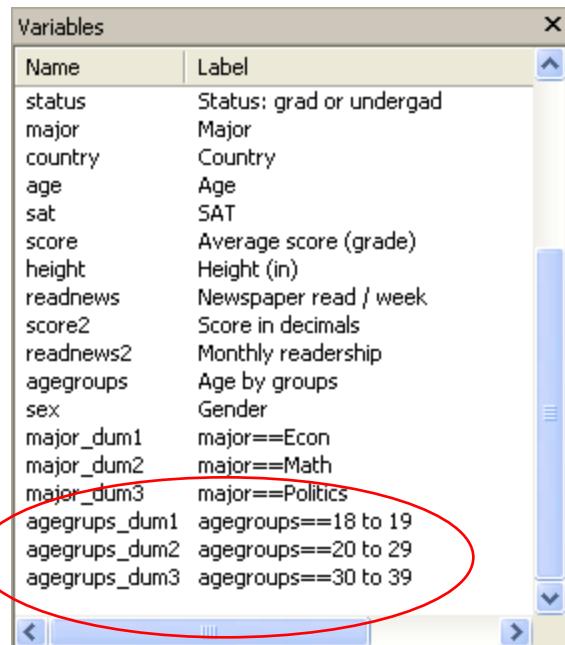

tab1 major_dum1 major_dum2 major_dum3			
-> tabulation of major_dum1			
major==Econ	Freq.	Percent	Cum.
0	20	66.67	66.67
1	10	33.33	100.00
Total	30	100.00	
-> tabulation of major_dum2			
major==Math	Freq.	Percent	Cum.
0	20	66.67	66.67
1	10	33.33	100.00
Total	30	100.00	
-> tabulation of major_dum3			
major==Politics	Freq.	Percent	Cum.
0	20	66.67	66.67
1	10	33.33	100.00
Total	30	100.00	40

Here is another example:

```
tab agregroups, generate(agegrups_dum)
```

Age by groups	Freq.	Percent	Cum.
18 to 19	10	33.33	33.33
20 to 29	9	30.00	63.33
30 to 39	11	36.67	100.00
Total	30	100.00	

Check the 'variables' window, at the end you will see three new variables. Using `tab1` (for multiple frequencies) you can check that they are all 0 and 1 values

agegrups==	Freq.	Percent	Cum.
18 to 19	20	66.67	66.67
1	10	33.33	100.00
Total	30	100.00	
-> tabulation of agegrups_dum1			
agegrups==	Freq.	Percent	Cum.
20 to 29	21	70.00	70.00
1	9	30.00	100.00
Total	30	100.00	
-> tabulation of agegrups_dum2			
agegrups==	Freq.	Percent	Cum.
30 to 39	19	63.33	63.33
1	11	36.67	100.00
Total	30	100.00	
-> tabulation of agegrups_dum3
